RESEARCH REPORT

Music Ability Helps Reading

By ANN LUKITS
Feb. 18, 2013 4:25 p.m. ET

Playing a musical instrument from a young age appears to create new pathways in the brain that process written words and letters and may help children with reading disorders such as dyslexia, says a study in the journal Neuropsychologia. Musicians generally outperform nonmusicians on cognitive tests, but little is known about the effects of reading musical notes on the brain's circuitry as it relates to reading, researchers said.

Playing a musical instrument from a young age appears to create new pathways in the brain that process written words and letters and may help children with reading disorders such as dyslexia. ILLUSTRATION BY IZAR COHEN

Fifteen professional musicians who had played an instrument since childhood and 15 control subjects who couldn't read music participated in two experiments in Milan. Subjects were 26 to 31 years old. In one experiment, subjects pressed a button if they recognized the notes E, F, G, A and B (mi, fa, sol, la and ti on the musical scale) which randomly appeared in 300 short musical scores flashed on a computer screen. In the other experiment, they pressed the button when they spotted the letters B, G, L, M and S

music measures were selected from Mozart and Schumann pieces for piano and for violin.

CAMERA DEI DEPUTATI N. 4673

PROPOSTA DI LEGGE

d'iniziativa del deputato MARROCU

Introduzione della pratica musicale e canora nelle scuole primarie

Presentata il 3 ottobre 2017

ONOREVOLI COLLEGHI ! – La presente proposta di legge nasce dall'esigenza di promuovere l'insegnamento della pratica musicale in modo progressivo coniugando la formazione di ordine intellettuale-disciplinare con quella artistica e musicale, a partire dalla scuola primaria, con il supporto di docenti adeguatamente formati e in possesso di titoli specifici nonché di giovani musicisti provenienti dalla carriera accademica abilitati alla professione didattica.

La proposta di legge intende:

a) favorire la diffusione della pratica della musica nell'ultimo triennio della scuola primaria.

Quello che si vuole introdurre con la tico della musica, quale valido strumento per contrastare il disagio giovanile, l'abbandono degli studi e la dispersione scolastica, nonché favorire l'inclusione e l'integrazione;

d) valorizzare lo studio pratico della musica.

La riforma dell'istruzione musicale in Italia è stata varata nel 1999 e oggi i conservatori di musica sono considerati, al pari delle università, istituzioni abilitate a rilasciare un titolo di studio del medesimo

come un adulto emotivamente azzoppato ».

Un'altra indagine scientifica importante è quella del dipartimento di psicologia dell'università di Milano-Bicocca condotta su quindici musicisti (pianoforte, violino, violoncello, tromba, clarinetto, flauto, organo, composizione, direzione d'orchestra) del conservatorio Verdi di Milano e su altrettante persone con nessuna competenza musicale.

La ricerca dimostra che chi è in grado di leggere il pentagramma ha una « marcia in più »: nel cervello dei musicisti, infatti, si attiva un'area del linguaggio solitamente « spenta » nelle altre persone.

La ricerca, pubblicata sulla rivista scientifica « *Neuropsychologia* » e condotta in collaborazione con il Consiglio nazionale delle ricerche presso il laboratorio di elettrofisiologia cognitiva della Bicocca, può avere applicazioni positive anche nella cura della dislessia.

« È noto che imparare a suonare bene uno strumento musicale – spiega Alice Mado Proverbio, docente di psicobiologia e psicologia fisiologica e coordinatrice dello studio – modifica la connettività cerebrale e la struttura funzionale del cervello, sia a livello di materia grigia che di materia bianca, velocizzando il *transfer* inter-emisferico, migliorando il controllo e la coordinazione motoria e l'elaborazione uditiva dei suoni ». « Noi abbiamo dimostrato che il cervello dei musicisti che hanno iniziato a studiare musica da piccoli, entro gli 8 anni, è anche più veloce nel riconoscere le parole. Per farlo, abbiamo confrontato l'elaborazione visiva delle note e delle parole in 30 persone destrimani, registrando la loro attività bioelettrica sincronizzata (Erp) in risposta a parole e note in un pentagramma ».

- Secondo i ricercatori fra i sei e gli otto anni di età ci sarebbe infatti una vera e propria «finestra sensibile», durante la quale un «allenamento musicale» riesce a interagire con il normale sviluppo cerebrale modificandolo in positivo, producendo cambiamenti a lungo termine con effetti vantaggiosi sulle abilità motorie, psicologiche e psicofisiche.
- «Favorire la diffusione della pratica musicale e canora nelle scuole primarie a partire dalla prima classe della scuola primaria con l'inserimento dello studio di uno strumento musicale o del canto individuale quale materia curricolare»
- «A partire dall'anno scolastico 2018/2019 per tutti i bambini iscritti alla prima classe della scuola primaria lezioni individuali di 30 minuti per 25 settimane. Il percorso poi proseguirà fino alla quinta classe.»

CONTROLLO MOTORIO

Pollice mano sinistra
D1 inattivo
Mignolo sinistro D5
molto più stimolato
rispetto ai controlli

La pratica musicale a lungo termine aumenta l'area della corteccia motoria responsabile del controllo delle dita dei violinisti (Elbert et al., 1995) e dei pianisti (Meister et al., 2005).

Increased Cortical Representation of the Fingers of the Left Hand in String Players

Thomas Elbert, Christo Pantev, Christian Wienbruch,
Brigitte Rockstroh, Edward Taub

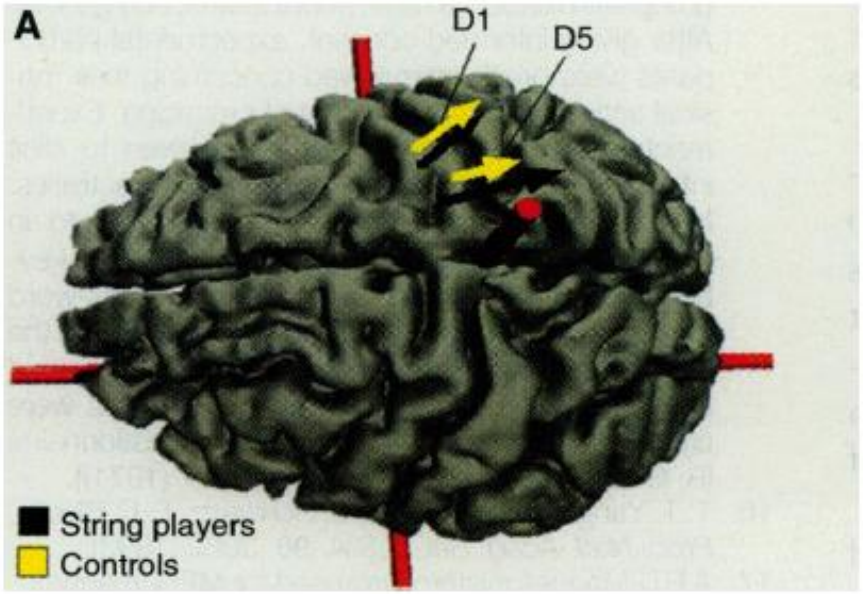

Fig. 1. (**A**) Equivalent current dipoles elicited by stimulation of the thumb (D1) and fifth finger (D5) of the left hand are superimposed onto an MRI (magnetic resonance imaging) reconstruction of the cerebral cortex of a control, who was selected to provide anatomical landmarks for the interpretation of the MEG-based localization. The arrows represent the location and orientation of the ECD vector for each of the two digits averaged across musicians (black) and controls (yellow). The length of the arrows represents the mean magnitude of the dipole moment for the two digits in each group. The average locations of D5 and D1 are shifted medially for the string players compared to

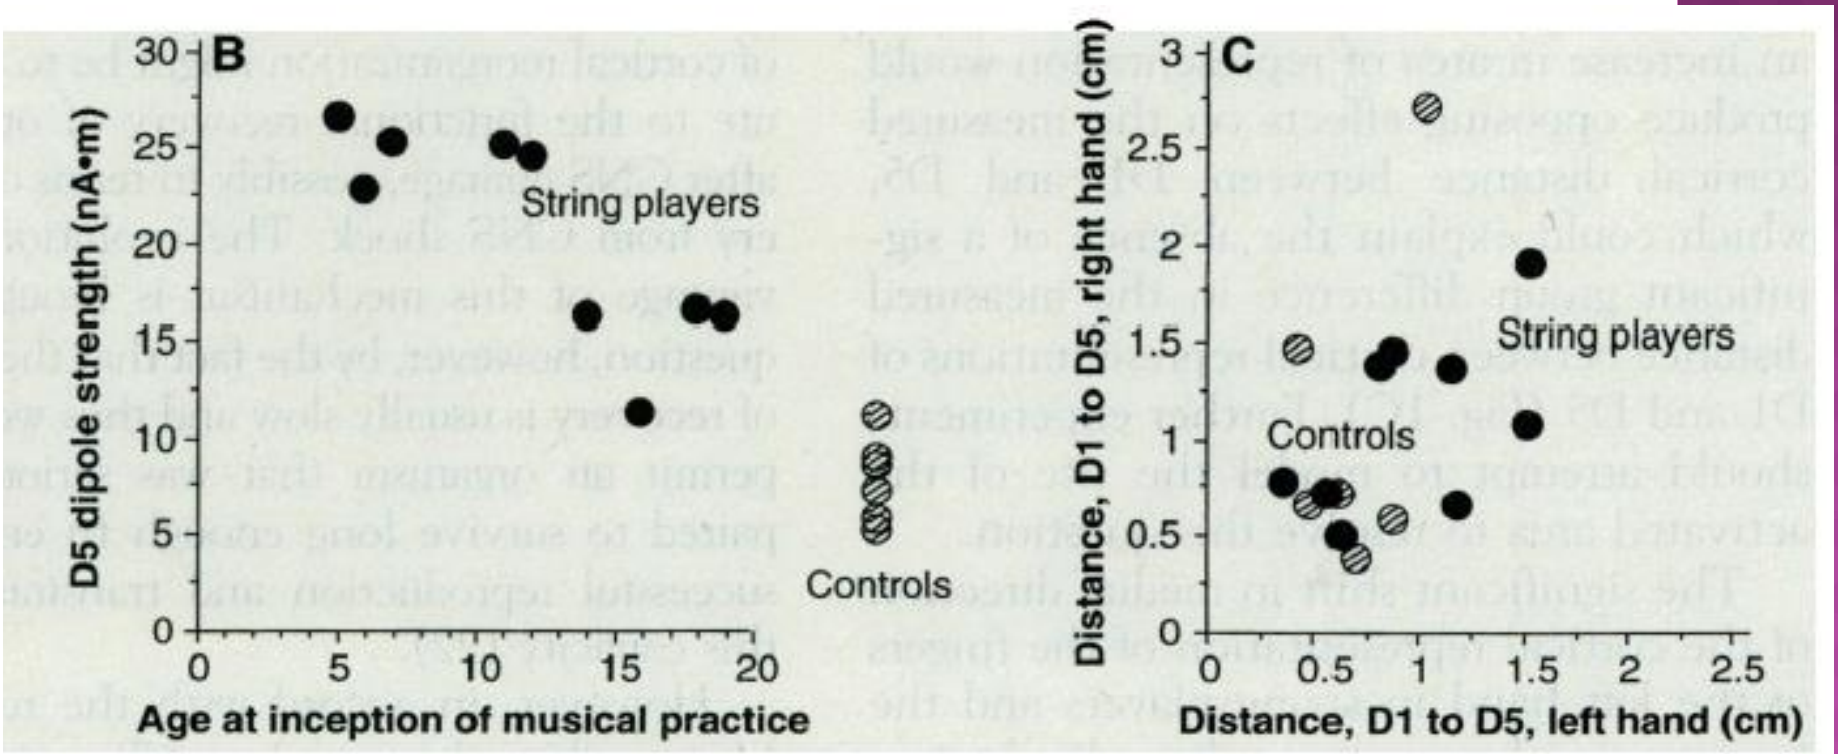
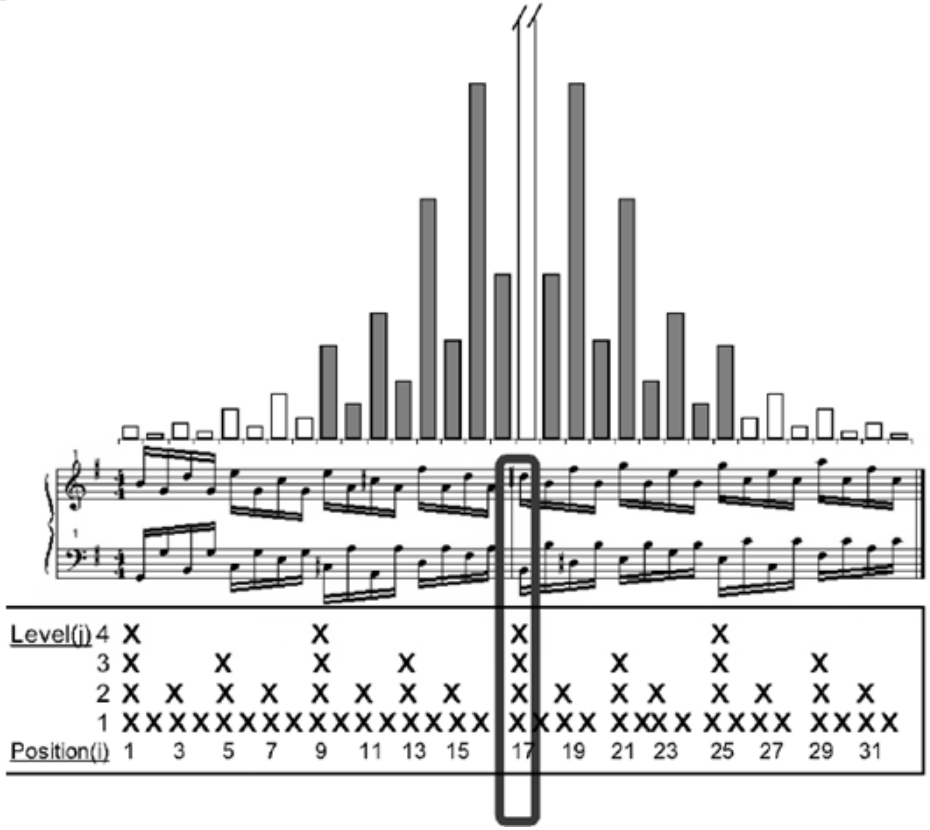
During the experimental session, somatosensory stimulation was delivered to the first digit and, in separate runs, to the fifth digit of either hand. Stimulation consisted of light superficial pressure applied by means of a pneumatic stimulator



PIANIFICAZIONE, PROGRAMMAZIONE

P. Q. Pfordresher. C. Palmer. M. K. Jungers/Cognitive Science 31 (2007)



Il cervello di un musicista è in grado di produrre 1200 movimenti al minuto: ogni movimento viene programmato 500 millisecondi prima dell'esecuzione

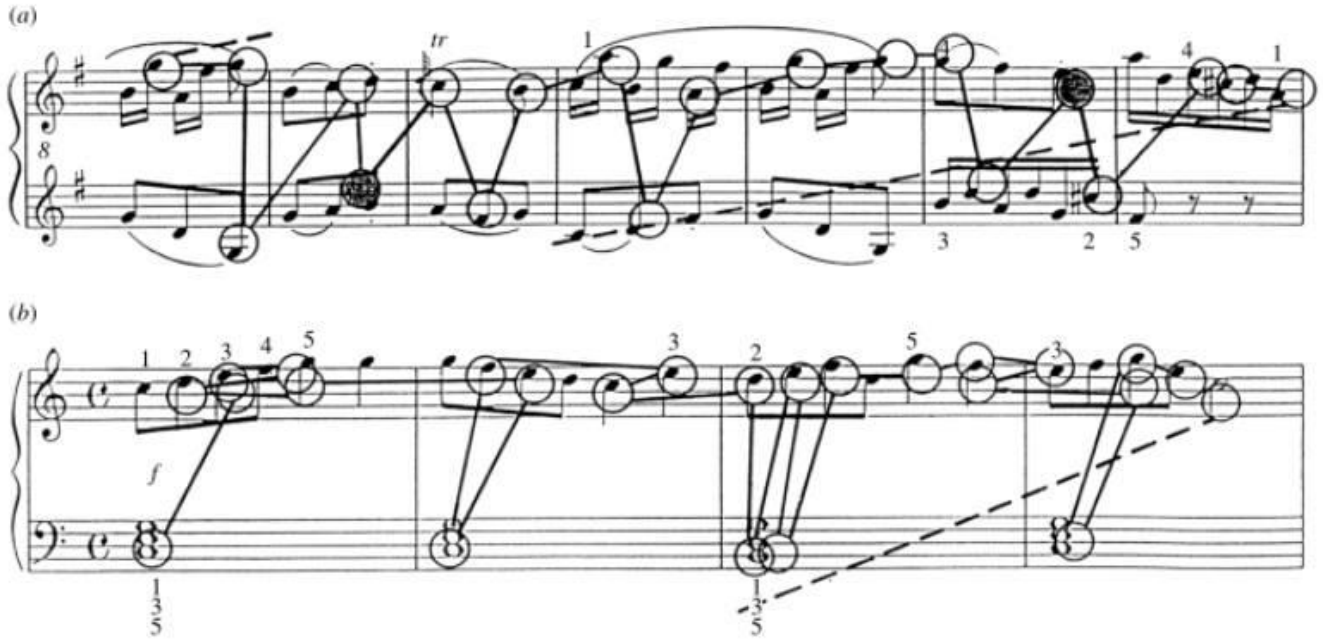


Figure 2. (*a*) One line of a piece by Scarlatti, showing the positions of fixations on the page during sight-reading by a professional subject (D.T.). Circles indicate fixation position and adjoining lines indicate saccades. Filled circles indicate that the next

[1]*Division Neuropsychology, Institute of Psychology, University of Zurich, Switzerland*

whole-brain functional connectivity during resting state in a sample of 15 string players and 15 nonmusicians.

Musicians demonstrate **increased intra- and interhemispheric functional connectivity** between those brain regions that are typically involved in music perception and production, such as the auditory, the sensorimotor, and prefrontal cortex as well as Broca's area.

Connectivity within this specific network was positively related to musical skill and the total number of training hours.

L'attitudine musicale è stata misurata con il test AMMA: i soggetti devono decidere se due brevi sequenze di pianoforte sono uguali o ritmicamente/armonicamente diverse

A) I punteggi al test correlano con il numero di ore di studio (x mille)
B) Con la connettività
C) Il numero di ore di training con la connettività
